Process Pack

As Is Process, To Be Process & Gap Analysis

Service Flow

Customer Service Improvement & Project Delivery Plan

Prepared for: NovaCare Services

Prepared by: Maleesha Nanayakkara, Business Analyst & Project Manager (Intern)
Codezela Career Accelerator — Business Analysis & Project Management Internship

1. Purpose

This document maps how service requests are handled today, defines the improved future-state process, and explains the gap between the two. It supports the requirements and user stories defined in the Requirements Pack.

2. As Is Process

Today, a service request moves through an unstructured, manual flow with no single source of truth:

1. Customer calls	2. Staff notes request	3. Message technician	4. Manual follow-up	5. Close in Excel

- Requests originate through phone, WhatsApp or in person, with no consistent intake point.
- Notes are handwritten or typed into whichever tool is convenient at the time.
- Technicians are messaged individually, often without full customer or address detail.
- Status is tracked only in the admin staff member's memory or a personal notebook.
- Completion is recorded in Excel, often after a delay, with inconsistent detail.

3. To-Be Process

ServiceFlow introduces a single, trackable workflow from first contact to completion:

1. Request created	2. Details checked	3. Staff assigned	4. Status updated	5. Report visible

- Every request is created in ServiceFlow at first contact, with mandatory core details.
- Admin checks and validates details (address, issue, contact number) before scheduling.
- Staff, date, time, and priority are assigned directly in the system.

- Status is updated at each stage (Checked → Scheduled → In Progress → Completed), giving a live audit trail.
- Managers see real-time reporting without needing to ask staff for updates.

4. Detailed Core Workflow

This is the most important business flow in the project. Every requirement, user story and acceptance criterion in the Requirements Pack supports it:

1. New request	2. Check details	3. Assign staff	4. Schedule visit	5. Update status	6. Complete request

Example: a customer calls to report an air-conditioner issue. Admin creates a request, checks the address, assigns a technician, schedules the visit, records progress and closes the request after completion.

5. Gap Analysis

Current Gap (As-Is)	Future State (To-Be)	Change Required
Requests scattered across calls, WhatsApp, and Excel	One central request record	Single intake and logging step for all channels
No clear ownership of tasks	Every request has an assigned staff member	Mandatory staff assignment before scheduling
Status not consistently tracked	Defined status flow (New → Completed)	Enforced status workflow with business rules
Customers must chase updates	Contact-notes history visible to admin	Structured contact log per request
No workload/overdue visibility for managers	Manager dashboard with live counts	Reporting view built on request status data

6. Process Notes for the Build Team

- The to-be workflow should be treated as the primary user journey when designing screens and navigation.
- Status transitions should be enforced by the system (business rules), not left to user discipline alone.
- The gap analysis should be used to validate that the final build addresses every identified gap.
